

Drug Overdose Deaths Involving Fentanyl, 2011–2016

by Merianne Rose Spencer, M.P.H., Margaret Warner, Ph.D., and Brigham A. Bastian, B.S., National Center for Health Statistics; James P. Trinidad, M.P.H., M.S., U.S. Food and Drug Administration; and Holly Hedegaard, M.D., M.S.P.H., National Center for Health Statistics

Abstract

Objectives—Fentanyl, a synthetic opioid, has been increasingly identified in drug overdose deaths. This report describes trends in drug overdose deaths involving fentanyl by demographic characteristics and geographic regions from 2011 through 2016.

Methods—Drug overdose deaths were identified from the National Vital Statistics System—Mortality (NVSS–M) multiple cause-of-death files (2011–2016) using *International Classification of Diseases, 10th Revision* underlying causes of death (codes X40–X44, X60–X64, X85, or Y10–Y14). NVSS–M records for drug overdose deaths were linked with literal text from death certificates. Drug overdose deaths involving fentanyl were identified using a methodology established collaboratively by the National Center for Health Statistics and U.S. Food and Drug Administration—referred to as the Drugs Mentioned with Involvement (DMI) methodology—supplemented with search terms identified using text analytics software. Fentanyl involvement was determined by the presence of any string term or phrase listing fentanyl, or any fentanyl metabolite, precursor, analog, or misspelling identified in the death certificate literal text fields (i.e., the causes of death from Part I, significant conditions contributing to death from Part II, and a description of how the injury occurred). Trends were evaluated using the National Cancer Institute's Joinpoint Regression Program.

Results—The number of drug overdose deaths involving fentanyl was stable in 2011 (1,663) and 2012 (1,615), and began to increase in 2013, rising to 18,335 deaths in 2016. The age-adjusted rate increased from 0.5 per 100,000 standard population in 2011 to 5.9 per 100,000 in 2016, with the increase starting in 2013 (0.6 in 2013 to 1.3 in 2014 and 2.6 in 2015). Numbers and rates increased for all sex, age, and racial and ethnic subgroups, and most public health regions. Adjustment for improved drug

reporting over the study period did not change the trend patterns observed.

Conclusions—This report illustrates the rise in drug overdose deaths involving fentanyl from 2011 through 2016 nationally, and by age, sex, race and ethnicity, and public health region. Understanding national trends and patterns for drug overdose deaths involving fentanyl may inform public health policies and practices.

Keywords: National Vital Statistics System • national trends • mortality • death certificate literal text

Introduction

Fentanyl is a synthetic opioid that has been involved increasingly in drug overdose deaths (1–11). In 2011 and 2012, fentanyl was involved in roughly 1,600 drug overdose deaths each year, but from 2012 through 2014, the number of drug overdose deaths involving fentanyl more than doubled each year (1). State-based analyses suggest that the recent increase in overdose deaths involving fentanyl may be related to increased availability of illicitly manufactured fentanyl (3,4,9–11). Illicitly manufactured fentanyl includes various analogs (e.g., acetylfentanyl, carfentanil, furanyl fentanyl) that vary in potency and can be lethal in very low concentrations (3).

National mortality statistics on drug overdose deaths have traditionally used the *International Classification of Diseases, 10th Revision* (ICD–10) to classify and monitor drugs involved in deaths (12). However, ICD–10 is limited to broader categories (e.g., synthetic opioids other than methadone) that make it difficult to identify deaths involving specific drugs of interest (e.g., fentanyl or illicitly manufactured fentanyl analogs). The National Center for Health Statistics (NCHS) and the U.S. Food and Drug Administration (FDA) collaboratively developed methods, referred to as the Drugs Mentioned with Involvement (DMI) methodology, to analyze literal text data from death

certificates to identify specific drugs involved in deaths (13). A recent study using the DMI methodology found that fentanyl was the ninth most frequently mentioned drug involved in overdose deaths in 2013 and the most frequently mentioned drug in 2016 (2). It also showed that deaths involving fentanyl often involved other drugs. For example, in 2016, nearly 70% of deaths involving fentanyl also involved one or more other drugs, such as heroin or cocaine (2).

This report describes the trends in drug overdose deaths involving fentanyl from 2011 through 2016, using mortality data from the National Vital Statistics System linked to literal text information from death certificates. Temporal trends, geographic patterns, and differences among demographic groups are presented.

Methods

Data sources

This descriptive study analyzed National Vital Statistics System mortality (NVSS–M) multiple cause-of-death data from 2011 through 2016. NVSS–M contains information extracted from death certificates on cause of death and demographic and geographic factors (14). The study population was limited to U.S. residents. Drug overdose deaths were identified using ICD–10 underlying cause-of-death codes X40–X44, X60–X64, X85, and Y10–Y14. These underlying-cause codes identify the deaths due to acute toxicity from drugs (i.e., drug overdose) rather than to chronic exposure leading to death (e.g., liver toxicity) or adverse effects from therapeutic or prophylactic dosages of drugs. Drug overdose deaths include all intents (i.e., unintentional, suicide, homicide, and undetermined intent). Use of these underlying cause-of-death codes is consistent with other NCHS publications on drug overdose deaths and facilitates comparisons with other analyses using ICD–10-coded data (1,2,15).

NVSS–M records for drug overdose deaths were linked to literal text data from death certificates. The literal text is the written information provided by the medical certifier, usually a medical examiner or coroner in the case of drug overdose deaths, that describes the cause of death as well as other factors or circumstances that contributed to the death (16,17). Literal text from three fields of the death certificate—the causes of death from Part I, the other significant conditions contributing to death from Part II, and the description of how the injury occurred—was analyzed to identify the specific drugs involved in the overdose death.

Identifying drug overdose deaths involving fentanyl

This report used the DMI methodology (13) informed by the results from an exploratory analysis of the literal text using SAS Contextual Analysis software (18). The DMI methodology (13) searches the literal text fields of NVSS–M data for mentions of drugs and for terms that provide context about involvement of the drug in the death (i.e., whether the drug contributed to the death). Drugs mentioned in the death certificate literal text

are assumed to be involved in the death unless contextual information suggests otherwise (13). For example, “METHICILLIN RESISTANT STAPHYLOCOCCUS AUREUS INFECTION” does not suggest drug involvement in mortality, but rather a type of bacterial infection. Similarly, the phrase “NOT DRUG RELATED” clearly indicates that drugs were not involved in the death even though “DRUG” is included in the phrase.

To supplement the DMI methodology, SAS Contextual Analysis software (18) was used to identify additional search terms. Linguistic rules were defined to search for new drug misspellings; precursors; metabolites; analogs of fentanyl, including those containing special characters, numbers, and dashes; and to identify forms that may be illicit (e.g., acetylfentanyl, carfentanil) or are brand or prescription forms of fentanyl (e.g., duragesic, sufentanil, remifentanil). The additional search terms identified using the contextual software were incorporated into the DMI methodology and are described in the [Technical Notes](#). With the expanded list of search terms, the total number of drug overdose deaths identified as involving fentanyl was slightly higher than previously reported (7 deaths in 2011, 10 deaths in 2012, 14 deaths in 2013, and 23 deaths in 2014) (1).

Analysis

For this report, the label “drug overdose deaths involving fentanyl” includes drug overdose deaths involving fentanyl, whether prescription or illicitly manufactured, as well as deaths involving any fentanyl metabolites, precursors, or analogs as identified in the death certificate literal text (see [Technical Notes](#)). The numbers and rates for drug overdoses involving fentanyl were calculated and compared by demographic and geographic region. Bridged-race vintage postcensal resident population estimates were used to calculate death rates (14). Age-adjusted death rates were calculated using the direct method and the 2000 standard U.S. population (14). Unless otherwise noted, rates in the text refer to age-adjusted rates.

Geographic patterns in overdose deaths involving fentanyl are presented by the U.S. Department of Health and Human Services (HHS) 10 public health regions. These regions are used for public health prevention, preparedness, and agency-wide coordination of HHS programs and policies (19). These regions, excluding U.S. territories, are:

- Region 1—Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, Vermont
- Region 2—New Jersey, New York, New York City
- Region 3—Delaware, District of Columbia, Maryland, Pennsylvania, Virginia, West Virginia
- Region 4—Alabama, Florida, Georgia, Kentucky, Mississippi, South Carolina, Tennessee
- Region 5—Illinois, Indiana, Michigan, Minnesota, Ohio, Wisconsin
- Region 6—Arkansas, Louisiana, New Mexico, Oklahoma, Texas
- Region 7—Iowa, Kansas, Missouri, Nebraska

- Region 8—Colorado, Montana, North Dakota, South Dakota, Utah, Wyoming
- Region 9—Arizona, California, Hawaii, Nevada
- Region 10—Alaska, Idaho, Oregon, Washington

Trends in rates for drug overdose deaths involving fentanyl were evaluated using the National Cancer Institute's Joinpoint Regression Program Version 4.6.0.0 (20). Joinpoint software fitted weighted least-squares regression models to the rates on the log transform scale. Allowing one observed time point at each end and two for the middle line segments, the Grid Search Algorithm searched for a maximum of two joinpoints at an overall alpha level of $p < 0.05$ (21). Pairwise comparisons of trend segments among subgroups were also analyzed, with Bonferroni adjustment (20). Rates between subgroups were compared using a z test at the 0.05 level of significance (14). Unless otherwise stated, any mention of an increase in rates indicates a statistically significant change.

Assessment for improved reporting on death certificates

The ICD-10 multiple-cause codes T36–T50.8 provide information on the types of drugs or drug classes involved in the death. The ICD-10 multiple-cause code T50.9 indicates a nonspecific reference to a drug (e.g., “multidrug,” “polypharmacy,” “drug”). The percentage of deaths with an underlying cause of X40–X44, X60–X64, X85, or Y10–Y14 that had a multiple-cause code of T36–T50.8 is a measure of the specificity of reporting drugs or drug classes in drug overdose deaths. This measure was used to assess possible changes in reporting of specific drugs and drug classes through the years of the study. The percentage of drug overdose deaths coded with T36–T50.8 increased each year (75.0% in 2011, 76.0% in 2012, 77.9% in 2013, 80.7% in 2014, 83.1% in 2015, and 85.4% in 2016) (21,22).

To assess the possible impact of lower reporting of specific drugs in the years prior to 2016, an adjustment factor accounting for improved reporting of specific drugs over the time period was applied to each age-adjusted rate for drug overdose deaths involving fentanyl (i.e., by year, sex, age, race and ethnicity, and public health region). The adjustment factor assumed that the specificity of drug reporting had remained constant from 2011 through 2016 at the 2016 drug specificity rate; the adjustment factor was recalculated and applied to each age-adjusted rate for the stratified analyses (i.e., demographic and geographic groups). Results from this analysis show similar trends for both the observed and adjusted values (see [Technical Notes](#)). The following results reflect the numbers and rates based on observed values. The number of drug overdose deaths involving any particular drug in any particular year should be considered the minimum number, as there may be additional deaths in which the drug was involved but not specified on the death certificate literal text. All results should be interpreted in light of the improved reporting of specific drugs in the literal text over time.

Results

Number and percentage of drug overdose deaths involving fentanyl

Annually, the number of drug overdose deaths involving fentanyl was stable in 2011 (1,663) and 2012 (1,615), and began to increase in 2013 (1,919), rising to 18,335 deaths in 2016 ([Table 1](#)). From 2013 through 2016, the number of deaths approximately doubled each year. From 2011 through the third quarter of 2013, there were fewer than 500 fentanyl-involved deaths per quarter ([Figure 1](#), [Table 1](#)). Beginning in the last quarter of 2013 through 2016, the number of deaths involving fentanyl increased nearly every quarter to more than 5,800 deaths.

Crude and age-adjusted rates of drug overdose deaths involving fentanyl

The age-adjusted rate of drug overdose deaths involving fentanyl was 0.5 per 100,000 in 2011 and 2012, and approximately doubled each year from 0.6 (2013) to 1.3 (2014) to 2.6 (2015) to 5.9 (2016) ([Figure 2](#), [Table 2](#)). From 2011 through 2013, there was no statistical change in the age-adjusted rates, but from 2013 through 2016, the rates increased on average by about 113% per year. The crude rates were similar to the age-adjusted rates for the study period.

Rates of drug overdose deaths involving fentanyl by sex of decedent

For males, age-adjusted rates for drug overdose deaths were stable from 2011 through 2013, and then increased by 125.6% per year from 2013 through 2016 ([Figure 3](#), [Tables 2](#) and [3](#)). For females, the age-adjusted rates increased exponentially from 2011 through 2016. In 2011, 2012, and 2013, the rates for males and females were similar at 0.6 to 0.7 per 100,000 for males, and 0.4 to 0.5 for females. Starting in 2013, the rates diverged, with the rate for males increasing more rapidly than the rate for females. By 2016, the rate for males (8.6) was 2.8 times the rate for females (3.1).

Rates of drug overdose deaths involving fentanyl by age group

Exponential increases in rates from 2011 through 2016 were observed among all age groups ([Figure 4](#), [Tables 2](#) and [3](#)). The largest average annual percent change from 2011 through 2016 occurred among young adults aged 25–34 (100.0% per year) and 15–24 (93.9% per year). The smallest average annual percent change occurred among adults aged 65 and over (41.6% per year). The rate for adults aged 35–44 was stable from 2011 through 2013, then increased by 123.7% per year from 2013 through 2016. In 2016, the rates were highest among adults aged 25–34 and 35–44 at 13.4 and 11.4 per 100,000, respectively.

Figure 1. Number of drug overdose deaths involving fentanyl, by quarter: United States, 2011–2016

Rates of drug overdose deaths involving fentanyl by race and ethnicity

The age-adjusted rates for drug overdose deaths involving fentanyl increased exponentially among all the racial and ethnic subgroups examined (Figure 5, Tables 2 and 3). Rates for non-Hispanic white persons ranged from 0.7 to 0.8 per 100,000 from 2011 through 2013, then increased by 108.8% from 2013 through 2016. Non-Hispanic black persons had the largest annual percentage increase in rates from 2011 through 2016 (140.6% per year), followed by Hispanic persons (118.3% per year). Rates for non-Hispanic white persons were greater than other subgroups throughout the study period. The rates for non-Hispanic black and Hispanic persons were similar from 2011 through 2013, then diverged from 2014 through 2016. In 2016, the rates were highest among non-Hispanic white persons (7.7), followed by non-Hispanic black (5.6) and Hispanic (2.5) persons.

Rates of drug overdose deaths involving fentanyl by public health region

Rates of drug overdose deaths involving fentanyl increased exponentially from 2011 through 2016 for most public health regions (Figure 6, Tables 2 and 3). The greatest rate increases were in Region 1 (CT, ME, MA, NH, RI, and VT), Region 2 (NJ, NY, and NYC), Region 3 (DE, DC, MD, PA, VA, and WV), and Region 5 (IL, IN, MI, MN, OH, and WI), which increased 113.9%, 110.9%, 103.6%, and 102.2% per year, respectively. Rates were similar across all public health regions in 2011. In 2016, the rates for Regions 1, 2, 3, 4, and 5 were higher than for Regions 6, 8, 9, and 10. In 2016, rates ranged from 0.8 per 100,000 (Region 9) to 19.8 (Region 1).

Discussion

This report illustrates the rise in drug overdose deaths involving fentanyl in the United States from 2011 through 2016. The number of drug overdose deaths involving fentanyl increased from 1,663 in 2011 to 18,335 in 2016. Beginning in the fourth quarter of 2013, the number of deaths increased every quarter. From 2013 through 2014, the death rate more than doubled,

Figure 2. Crude and age-adjusted rates for drug overdose deaths involving fentanyl, by year: United States, 2011–2016

nearly doubled again from 2014 through 2015, and more than doubled again from 2015 through 2016.

The rate of drug overdose deaths involving fentanyl increased exponentially for both sexes, with the rate increasing more rapidly for males than for females. Rates also increased exponentially across all age groups, with the greatest increases among those aged 15–24 and 25–34. Exponential increases were also seen for rates among race and ethnicity groups. Non-Hispanic black persons had the largest annual percentage increase in rates, followed by Hispanic persons, while in 2016, the rate was highest for non-Hispanic white persons. Rates increased exponentially for most public health regions, however, the increase was greatest in Regions 1, 2, 3, and 5 (i.e., East Coast and Upper Midwest).

Limitations

Monitoring national trends in drug overdose deaths depends on the quality and completeness of information provided on death certificates. Variation in death investigation, autopsy, and toxicology practices across medicolegal death investigation jurisdictions contributes to inconsistencies in how the manner and cause of death are reported (23,24). For example, differences in toxicological testing practices, such as when and how the

Figure 3. Age-adjusted rates for drug overdose deaths involving fentanyl, by sex of the decedent: United States, 2011–2016

testing is performed, which substances are tested for, and the interpretation of the test results, can impact whether fentanyl is detected and reported on the death certificate. Because of these limitations, the number of drug overdose deaths involving any particular drug in any particular year should be considered the minimum number, as there may be additional deaths in which the drug was involved but not specified on the death certificate literal text.

Variations in the way drug overdose deaths are reported on the death certificates, including the level of detail on the specific drugs involved, impacts comparability. Trends in rates should be interpreted in light of the improvements in the quality of the data during the study period. For example, some of the observed increases in the rates are likely attributable to improvements in reporting. During the study period, the reporting of at least one specific drug in the literal text improved from 75% of drug overdose deaths in 2011 to 85% of drug overdose deaths in 2016 (2,22). To account for improved reporting of specific drugs over the time period, an adjustment factor, which took into account what the drug overdose death rate involving fentanyl would have been had the drug specificity been uniform from 2011 through 2016, was applied to the rates. The adjustments for improved reporting did not change the patterns observed.

Figure 4. Rates for drug overdose deaths involving fentanyl, by age group: United States, 2011–2016

Figure 5. Age-adjusted rates for drug overdose deaths involving fentanyl, by race and ethnicity: United States, 2011–2016

Figure 6. Age-adjusted rates for drug overdose deaths involving fentanyl, by public health region: United States, 2011–2016

The absence of drug-specific information on the death certificate does not mean that fentanyl was not present; rather, it may suggest that toxicology tests were not performed or were inadequate to detect the drug. Also, new fentanyl analogs are being identified with increasing frequency and are often lethal in very low concentrations. Detection of these substances requires new testing materials and continuous recalibration of toxicology laboratory equipment (16), both of which can be complicated and expensive, thus further contributing to variation in death reporting across the country.

The need to understand the factors influencing overdoses and deaths involving fentanyl has resulted in collaboration among public health agencies, medical examiners and coroners, and public safety agencies. These collaborations will contribute to better detection and reporting on death certificates, which in turn, will help improve quality of local, state, and national vital statistics data.

Conclusion

Fentanyl is increasingly involved in drug overdose deaths nationally. This report uses NVSS–M data, enhanced with literal text from death certificates, to provide a picture of temporal trends, demographic characteristics, and geographic patterns of fentanyl-involved drug overdose deaths in the United States from 2011 through 2016.

NOTES: Drug overdose deaths are identified using *International Classification of Diseases, 10th Revision* underlying cause-of-death codes X40–X44, X60–X64, X85, and Y10–Y14. Deaths may involve other drugs in addition to fentanyl. Caution should be used when comparing numbers across years. The reporting of at least one specific drug or drug class in the literal text, as identified by multiple cause-of-death codes T36–T50.8, improved from 75.0% of drug overdose deaths in 2011 to 85.4% in 2016.

¹Geographic regions defined by the U.S. Department of Health and Human Services (HHS), which are used for prevention, preparedness, and agency-wide coordination of HHS programs and policies. Region 1 includes Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, and Vermont; Region 2 includes New Jersey, New York, and New York City; Region 3 includes Delaware, District of Columbia, Maryland, Pennsylvania, Virginia, and West Virginia; Region 4 includes Alabama, Florida, Georgia, Kentucky, Mississippi, South Carolina, and Tennessee; Region 5 includes Illinois, Indiana, Michigan, Minnesota, Ohio, and Wisconsin; Region 6 includes Arkansas, Louisiana, New Mexico, Oklahoma, and Texas; Region 7 includes Iowa, Kansas, Missouri, and Nebraska; Region 8 includes Colorado, Montana, North Dakota, South Dakota, Utah, and Wyoming; Region 9 includes Arizona, California, Hawaii, and Nevada; Region 10 includes Alaska, Idaho, Oregon, and Washington.

NOTES: Drug overdose deaths are identified using *International Classification of Diseases, 10th Revision* underlying cause-of-death codes X40–X44, X60–X64, X85, and Y10–Y14. Deaths may involve other drugs in addition to fentanyl. Caution should be used when comparing numbers across years. The reporting of at least one specific drug or drug class in the literal text, as identified by multiple cause-of-death codes T36–T50.8, improved from 75.0% of drug overdose deaths in 2011 to 85.4% in 2016.

SOURCE: NCHS, National Vital Statistics System, Mortality files linked with death certificate literal text.

Table 3. Trends in age-adjusted rates for drug overdose deaths involving fentanyl, by sex, age, race and Hispanic origin, and public health region: United States, 2011–2016

Technical Notes

Identification of fentanyl, fentanyl analogs, and misspellings on death certificate literal text fields

This report defines “drug overdoses involving fentanyl” as a drug overdose death involving fentanyl itself, including prescription fentanyl and illicitly manufactured fentanyl, as well as any fentanyl metabolites, precursors, and analogs identified in the death certificate text.

A search list for fentanyl was developed using the Scientific Working Group for the Analysis of Seized Drugs, which includes structurally confirmed reference materials generated by the United States Drug Enforcement Administration’s special testing and research laboratory, and any monographs authored by the Forensic Drug Review and the Center for Forensic Science Research & Education (25). This list, combined with fentanyl analogs found in the U.S. Food and Drug Administration’s (FDA) Substance Registration System (26) as of August 2017, is listed below. This search list was used to conduct an initial search of possible fentanyl terms mentioned in the literal text on death records from 2010 through 2016 using SAS Contextual Analysis software (18). If the term was found, a second analysis was conducted to identify misspellings of the term. The National Center for Health Statistics and FDA’s Drugs Mentioned with Involvement (DMI) methodology was updated to include the new terms identified.

Fentanyl analogs identified in the literature, reports, and other sources are listed below:

3-METHYLFENTANYL*, 3-METHYLTHIOFENTANYL*, 4-ANPP*, 4-CLORO-ISOBUTYLFENTANYL*, 4-FLUOROBUTYRYLFENTANYL*, 4-FLUORO-ISOBUTYRYLFENTANYL*, 4-MeO-BUTYRYLFENTANYL*, ABSTRAL, FENTANIL*, ACETYL-ALPHA-METHYLFENTANYL, ACETYLFENTANYL*, ACRYLFENTANYL*, ACRYLOYLFENTANYL*, ACTIQ, ALFENTANIL*, ALPHA-METHYLTHIOFENTANYL, BENTANYL, BETA-HYDROXY-3-METHYLFENTANYL, BETA-HYDROXYFENTANYL, BETA-HYDROXYTHIOFENTANYL*, BUTYRYLFENTANYL*, CARFENTANIL*, CROTONYLFENTANYL, CYCLOPROPYLFENTANYL, DESPROPIONYL-2-FLUOROFENTANYL, DESPROPIONYLFENTANYL*, DURAGESIC*, FENTANYL*, FENTORA, (2- or 3-) FURANYLFENTANYL*, IONSYS, ISOBUTYRYLFENTANYL*, LAZANDA, LOFENTANIL, META-FLUOROFENTANYL, METHOXYACETYLFENTANYL*, MIRFENTANYL, NORFENTANYL*, N-PHENETHYL-4-PIPERIDONE (NPP)*, OCFENTANIL, ONSOLIS, ORTHO-FLUOROFENTANYL*, PARA-CHLOROFENTANYL, PARA-CHLOROISOBUTYRFENTANYL, PARA-FLUOROBUTYRYL-FENTANYL*, PARA-FLUOROFENTANYL*, PARA-FLUOROISOBUTYRYLFENTANYL, PARA-METHODOXYBUTYRYLFENTANYL, REMIFENTANIL*,

SUBLIMAZE, SUBSYS, SUFENTANIL*, TETRAHYDROFURANYLFENTANYL, THIOFENTANYL, VALERYLFENTANYL*

A comprehensive review for misspellings was conducted for terms with an asterisk because an exact pattern match of more than five records was found in the literal text fields for National Vital Statistics System—Mortality data for years 2010–2016.

The terms were grouped into broader fentanyl categories for reporting purposes. The term groupings are detailed in [Table I](#) according to the DMI methodology.

Methods for calculating and applying adjustment factor in trend analysis

The reporting of at least one specific drug involved in drug overdose deaths improved from 75.0% in 2011 to 85.4% in 2016 (2,22). Trend estimates may be impacted by the improvement in reporting that occurred during the study period. To assess the possible impact of the improved reporting of specific drugs in the years leading up to 2016, an adjustment factor was applied to each rate (i.e., by year, sex, age, race and ethnicity, and public health region) to calculate an adjusted rate. Drug specificity was determined for each year of the study as the percentage of drug overdose deaths with at least one *International Classification of Diseases, 10th Revision* (ICD-10) multiple cause-of-death code in the range of T36–T50.8. Drug specificity was calculated for each demographic and geographic subgroup in years 2011–2016 by taking the number of drug overdose deaths with codes T36–T50.8 divided by the number of drug overdose deaths in a given region and year ([Table II](#)). For example, in 2011, there were 41,340 drug overdose deaths, and among these, 30,993 of the deaths had a multiple-cause code of T36–T50.8, thus resulting in 75.0% drug specificity among drug overdose deaths in 2011. The same calculation applies to those in specific subgroups; in 2011, there were 2,941 drug overdose deaths among Hispanic persons, and 2,300 drug overdose deaths had a multiple-cause code of T36–T50.8, resulting in 78.2% drug specificity.

The adjustment factor ([Table II](#)) was calculated using the following assumptions for each year and subgroup: 1) from 2011 through 2015, the percentage of deaths with one or more drugs specified was equal to the percentage in 2016, and 2) the proportion of deaths involving fentanyl was the same for deaths that identified one or more specific drugs as for deaths that did not identify a specific drug. For example in 2011, there were 41,340 drug overdose deaths; the drug specificity was 75.0%, and 1,663 deaths involved fentanyl for an age-adjusted rate (AAR) of 0.53 per 100,000 standard population. To adjust for improved reporting:

1. Calculate the difference in percentage reporting in 2016 compared with 2011 (i.e., 85.4% – 75.0% = 10.4%).
2. Multiply the difference in percentage reporting by the total number of drug overdose deaths in 2011 (i.e., 10.4% * 41,340 = 4,299.36).
3. Calculate the proportion of drug overdose deaths involving fentanyl among drug overdose deaths with one or more

drugs specified in 2011 (i.e., $1,663 / [75.0\% \cdot 41,340] = 0.053636$).

4. Multiply the results from step 2 by the results from step 3 (i.e., $4,299.36 \cdot 0.053636 = 230.6$).
5. Calculate the adjustment factor by dividing the adjusted total drug overdose deaths involving fentanyl by the observed number of drug overdose deaths involving fentanyl (i.e., $(1,663 + 230.6) / 1,663 = 1.14$).
6. Calculate the adjusted AAR by multiplying the 2011 adjustment factor by the 2011 AAR rate (i.e., $0.53 \cdot 1.14 = 0.60$).

Table III shows the observed and adjusted age-adjusted death rates for each year by demographic and geographic group. The observed rates and number of drug overdose deaths involving any particular drug in any particular year should be considered the minimum number, as there may be additional deaths in which the drug was involved but not specified on the death certificate literal text. Observed and adjusted age-adjusted death rates resulted in similar findings after application of the adjustment factor (Table III).

ALFENTANIL	ALFENTANIL
BUTYRFENTANYL	BUTRYL FENTANYL, BUTYL FENTANYL, BUTYR FENTANYL, BUTYRFENTANYL, BUTYRYL FENTANYL, BUTYRYLFENTANUL, BUTYRYLFENTANYL
CARFENTANIL	CARENTANIL, CARENTANYL, CARFENTAIL, CARFENTANI, CARFENTANIL, CARFENTANILI, CARFENTANILTOXICITY, CARFENTANTANIL, CARFENTANYL, CARFENTENIL, CARFENTIL, CARFENTINAL, CARFENTINIL, CARRENTANIL, CARTENTANIL
DESPROPIONYL FLUROFENTANYL	DESPROPIONYL FLUROFENTANYL

See footnotes at end of table.

Table I. Fentanyl groupings, as detailed in the Drugs Mentioned with Involvement methodology identified from National Vital Statistics System—Mortality literal text, 2010–2016—Con.

Principal variant ¹	Search terms
DEPROPIONYLFENTANYL	ANILINE N PHENETHYLPYPERIDINE, ANILINO N PHENETHYPIPERIDINE, ANILINO N PHENETHYL PIPERIDINE, ANILINO N PHENETHYLPENDINE, ANILINO N PHENETHYLPIDERDINE, ANILINO N PHENETHYLPYPERIDINE, ANILINO PHENETHYPIPERIDINE, ANILIO N PHENETHYLPYPERIDINE, ANILO N PHENETHYLPYPERIDINE, ANPP, DEPROPIONLFENTANYL, DEPROPIONYL FENTANYL, DEPROPIONYLFENTANYL, DESOROPIONYL FENTANYL, DESPROPIONY FENTANYL, DESPROPIONYFENTANYL, DESPROPIONYL AND FLUORISOBUTYRYL FENTANYL, DESPROPIONYL ANILIO N PHENETHYLPYPERIDINE, DESPROPIONYL FENTANYL, DESPROPIONYLFENTANYL, DESPROPIOYL FENTANYL, DESPROPLONYL FENTNYL, DESPROPRIONYL FENTANYL, DESPROPRIONYLFENTANYL, FENTANYL ANALOGUES FURANYL PARAFLUROBUTYRYL AND DESPROPIONYL, N PHENETHYL PIPERIDINE, N PHENYL PHENYLETHYL PIPERIDIN AMINE
FURANYLFENTANYL+	ACETYL FURANYL FENTANYL, DURANYLFENTANYL, FENTANYL ANALOGUES FURANYL PARAFLUROBUTYRYL AND DESPROPIONYL, FERANYL FENTANYL, FUNANYL FENTANYL, FURANULFENTANYL, FURANY FENTANUL, FURANY FENTANYL, FURANYFENTANYL, FURANYIFENTANYL, FURANYL FENTANYL, FURANYLFANTANYL, FURANYLFENTANTL, FURANYLFENTANYL, FURANYLFENTANYLM, FURANYLTENTANYAL, FURANYLTENTANYL, FURAYLFENTANY, FURAYLFENTANYL, FURFANYLFENTANYL, FURNYL FENTAYL, FURTANYL FENTANYL, FURYL FENTANYL, TURANYL FENTANYL
ISOBUTYRFENTANYL	ISOBUTYRYLFENTANYL
METHOXYACETYLFENTANYL	METHOXYACETYL FENTANYL
METHYLFENTANYL+	CIS METHYLFENTANYL
NORALFENTANIL	NORALFENTANIL
NORFENTANYL	NORENTANYL, NORFENTANLY, NORFENTANYL, NORFETANYL, NORPHENTANYL
ORTHO-FLUOROFENTANYL	ORTHO FLUOROFENTANYL
P-FLUOROFENTANYL	FLUORA FENTANYL, FLUOROFENTANYL, FLURODENTANYL, FLUROFENTANYL, FLUROROFENTANYL, PARA FLUROFENTANYL, PARAFLUROFENTANYL, PARAFLURO FENTANYL
REMIFENTANIL	REMIFENTANIL, REMIFENTANYL
SUFENTANIL	SUFENTANIL
AMBIGUOUS (FENTANYL or TEGAFUR)	FENTALY, FENTAYL, FENTYAL, FENTYL
AMBIGUOUS (NORALFENTANIL or NORFENTANYL)	NOAFENTANYL

¹The overarching label assigned to a drug, a drug class, or exposure not otherwise specified in the Drugs Mentioned with Involvement methodology. For example, terms such as “COCAIEN,” “COCAINE CRACK,” “COCAINE HYDROCHLORIDE,” and “COCAINETOXICITY” are all mapped to the principal variant “COCAINE.” In the case of drug overdose deaths involving fentanyl, all of the principal variants in this table were used to calculate the numbers and rates presented in this report.

SOURCE: NCHS, National Vital Statistics System, Mortality files linked with death certificate literal text.

Table II. Percent of drug overdose deaths with drugs specified, by sex, age, race and Hispanic origin, and public health region: United States, 2011–2016

Characteristic	Percent						Adjustment factor					
	2011	2012	2013	2014	2015	2016	2011	2012	2013	2014	2015	2016
All drug overdose deaths	75.0	76.0	77.9	80.7	83.1	85.4	1.14	1.12	1.10	1.06	1.03	1.00

¹Geographic regions defined by the U.S. Department of Health and Human Services (HHS), which are used for prevention, preparedness, and agency-wide coordination of HHS programs and policies. Region 1 includes Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, and Vermont; Region 2 includes New Jersey, New York, and New York City; Region 3 includes Delaware, District of Columbia, Maryland, Pennsylvania, Virginia, and West Virginia; Region 4 includes Alabama, Florida, Georgia, Kentucky, Mississippi, South Carolina, and Tennessee; Region 5 includes Illinois, Indiana, Michigan, Minnesota, Ohio, and Wisconsin; Region 6 includes Arkansas, Louisiana, New Mexico, Oklahoma, and Texas; Region 7 includes Iowa, Kansas, Missouri, and Nebraska; Region 8 includes Colorado, Montana, North Dakota, South Dakota, Utah, and Wyoming; Region 9 includes Arizona, California, Hawaii, and Nevada; and Region 10 includes Alaska, Idaho, Oregon, and Washington.

NOTE: Drug specificity is calculated by taking the number of drug overdose deaths (*International Classification of Diseases, 10th Revision* [ICD–10] underlying cause-of-death codes X40–X44, X60–X64, X85, and Y10–Y14) with ICD–10 multiple cause-of-death codes T30–T50.8, divided by the number of drug overdose deaths in a given region and year.

Acknowledgments

The authors would like to acknowledge the contributions of Lauren Rossen, Katherine E. Irimata, and Donald Malec of the National Center for Health Statistics, for their guidance on the trends analysis; and Bruce Goldberger at the University of Florida College of Medicine and Barry Logan at NMS Labs, for their expert toxicological input on fentanyl terms, analogs, derivatives, and other forms.
